Pipeline Validation Report

This report summarizes agreement between the pipeline's outputs (`p_*` columns) and manually-reviewed ground truth (`gt_*` columns) across a sample of court opinions. The sample excludes 8 rows with no usable ground truth (OCR garbage or no opinion available), leaving 215 rows. Figures below are the table and confusion-matrix outputs of `validation.py`.

1. Overall Agreement Rates

Agreement rate per field computed across all 215 rows. Doesn't distinguish pipeline struggles or, for Signer Role, whether a low rate reflects wrong answers versus "unclear" label.

For disposition, agreement uses a substring rule rather than exact string match to address multiple comma-separated dispositions for one opinion (e.g. `granted,denied`), while ground truth records a single value. A row counts as agreement if the ground-truth value appears anywhere in the pipeline's list.

	Agreement Rate	Correct/Total
Judge Name	60.9%	131/215
Signer Role	49.8%	107/215
Disposition	46.0%	99/215
Case Type	30.2%	65/215

2. Agreement Rates by Era

The same four fields broken down by the opinion's era (`pre-1980`, `1980-1989`, `1990-2019`).

	pre-1980	1980-1989	1990-2019
Judge Name	77.2% (44/57)	54.4% (37/68)	55.6% (50/90)
Signer Role	52.6% (30/57)	44.1% (30/68)	52.2% (47/90)
Disposition	45.6% (26/57)	51.5% (35/68)	42.2% (38/90)
Case Type	14.0% (8/57)	32.4% (22/68)	38.9% (35/90)

3. Agreement Rates by (Pipeline) Signer-Role

The same breakdown, but grouped by the pipeline's own signer_role guess (`district`, `magistrate`, or `unclear`). The Signer Role field itself is intentionally excluded from this table so there isn't a meaningless `unclear` cell. That comparison is handled separately in Sections 4 and 5.

	district	magistrate	unclear
Judge Name	78.9% (71/90)	46.5% (20/43)	48.8% (40/82)
Disposition	55.6% (50/90)	44.2% (19/43)	36.6% (30/82)
Case Type	24.4% (22/90)	44.2% (19/43)	29.3% (24/82)

4. Signer Role Accuracy (claimed rows)

Accuracy for rows where the pipeline gave an actual answer (`p_signer_role` = `district` or `magistrate`).

	Accuracy	Correct/Total
district	98.9%	89/90
magistrate	41.9%	18/43
Overall (claimed)	80.5%	107/133

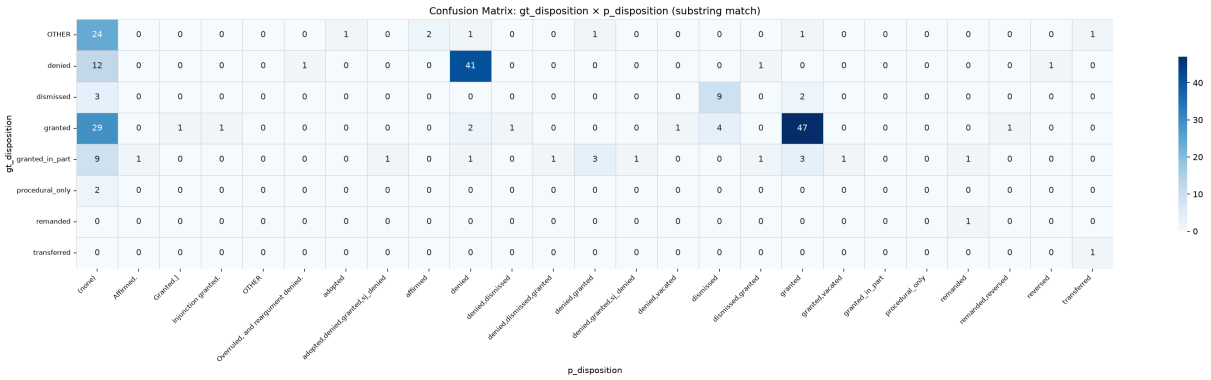

5. Signer Role Recovery (unclear rows)

Covers the rows the pipeline left as `unclear` (82 of 215). On these rows the pipeline made no prediction, so accuracy doesn't apply. Instead we're interested in how many of the rows which the pipeline found to be unclear were able to be recovered by the ground-truth findings. Note that all 82 were recovered.

	Count	Share of Unclear
district	48	58.5%
bankruptcy	17	20.7%
appellate_by_designation	7	8.5%
other	7	8.5%
magistrate	3	3.7%
Recovered (any role)	82	100.0%

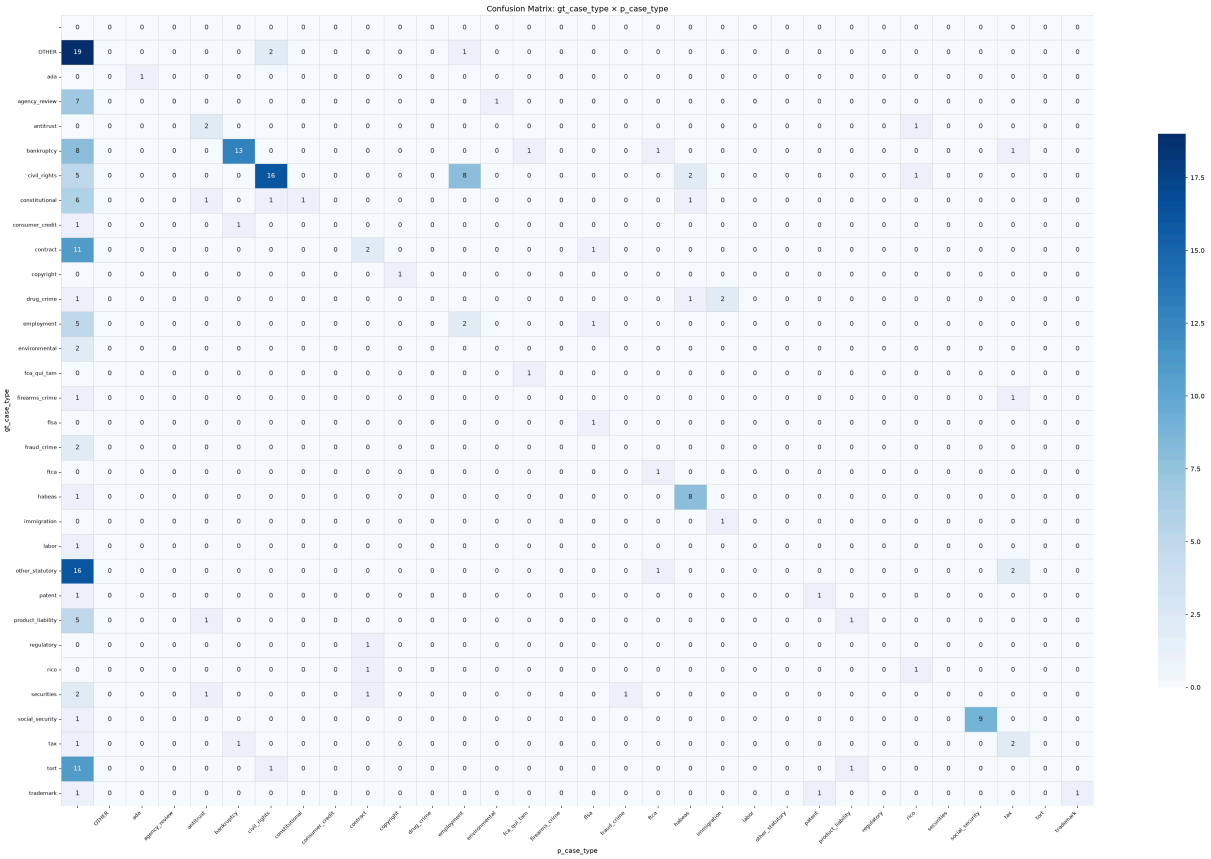

6. Confusion Matrix: Disposition

Row = ground truth disposition, column = what the pipeline output, cell = row count. Uses the same substring rule as Section 1. If the pipeline's comma-separated output contains the ground-truth value (e.g. pipeline `granted,vacated` vs. ground truth `granted`), that row is collapsed onto the diagonal cell rather than plotted as its own sparse row/column. Only where the pipeline's value doesn't contain the ground-truth value at all do we retain the raw comma-joined string as a column so the disagreement is still visible.

7. Confusion Matrix: Case Type

Row = ground truth case type, column = pipeline-predicted case type, cell = row count (no substring rule).

Confusion Matrix: gt_case_type × p_case_type
